A mixed source and its coefficient-norm probe

Same source, positive comparison

$Q_N = T(A_N)$

$\|Q_N\|_{\mathcal{J}} \le \mathrm{poly}(N)\, \phi(W_N A_N^{\mathrm{abs}})$

$W_N = \sum_{r=0}^{N-1} w_{N,r} \widehat{B}_r$

A_N^{abs} uses the same products and turns, with absolute values of the boundary coefficient arrays.

W_N is a norm probe, not an added crossing circle.

The original colors, index cutoffs and first Hermite normals remain in the estimate.

Syntax/estimate diagram, not a knot projection.
