

A joint complex domain

$\left|\mathrm{Re}\, x_1 - \frac{1}{2}\right| + \left|\mathrm{Re}\, x_2 - \frac{1}{2}\right| < \frac{1}{2}$

Pair degree and magnetic coordinate may both be complex. The channel remains an integer.

The global condition remains

One common frame must place every input and output in the domain, with the correct local sheet. A contributing cycle and a bound for the full sum require further proof.

This is the projection onto real parts. Imaginary parts are unrestricted; the uniform asymptotic holds on compact subsets. Dashed boundaries are excluded.
