Moving and combining signed twist blocks

Products are stacked from bottom to top. The four outside endpoints stay fixed.

1. Move the twist past a tangle

F is any two-strand tangle in the box.

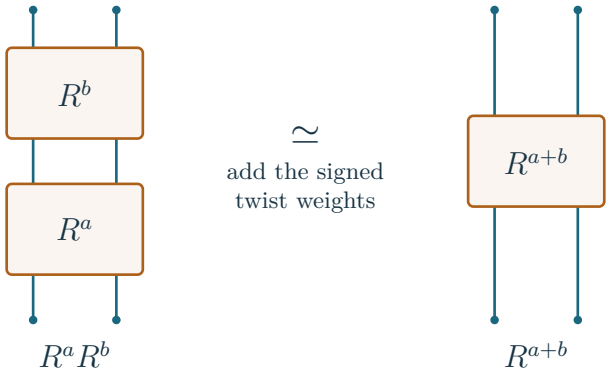

ρ is the half-turn about the stacking axis.

If a is even: $\rho^a(F) = F$.

If a is odd: $\rho^a(F) = \rho(F)$.

The rotation of F is part of the move.

2. Fuse adjacent twist blocks

Opposite twists cancel in pairs.

For example,

$(a + 2m) + (-2m) = a$.

Both written weights can be large while their net twist remains fixed.

The boxes retain their internal tangles and ordered attachments.
A slide does not exchange two arbitrary tangle boxes.
