The two sides of one crossing disk

Dashed circles are orthogonal to the three white circles on their respective sides.

The primitive pairing is a dilation

$$w = \frac{z - P_+}{z - P_-}$$

$$C(w) = R_0 w, \qquad R_0 = \rho_c/\rho_b$$

$$C_1 \mapsto C_0, \quad C_2 \mapsto C_3$$

$P_+ \mapsto 0$, while the selected eigenline P_- maps to ∞. The auxiliary meridian follows the reverse map C^{-1}.

Exact finite-circle example: $x = y = b = c = 1$, $\delta = 1/10$. The marked-line limit is treated separately in the text.
