

A count independent of bridge width

The geometric strip conditions place both sphere flags inside C. A generic line exits through exactly two facets.

At each exit, the three actual prefix diagonals have a nonnegative relation summing to zero. That factor fails strict physical support.

All other factors now have the selected full physical packet. The two exits can be placed at one crossing-circle edge. Its exact local recoupling block is retained. A sharp contraction and global period estimate are still needed in this general-plat route.

The strict Conway-tree volume theorem uses separate source estimates.

Schematic planar section in the space of normalized face normals. The dashed circle is the section of the ideal sphere. This is not a picture of the original hyperbolic polyhedron.
