The preferred longitude on the filled cusp

One fixed Euclidean lattice; two choices of longitude

$$\lambda_{\text{fill}} = \lambda_{\text{aug}} + c\mu, \qquad c = \sum_i p_i \ell_i^2$$

Illustrated case: one $p = 1$ filling with linking number $\ell = \pm 2$, so $c = 4$.

λ_{aug} is the image of the augmented longitude on this filled cusp. Both shaded parallelograms are fundamental domains for the same lattice.
