Which source bounds retain the volume?

One original marked source, seventeen regions

Width 3; word $O(EO)^3$, with $O = (1,3)$, $E = (0,2,4)$.
All faces, targets and the two protected zeros stay shared.

One RIGHT anchor; all other regions bounded in full

$$\inf_L C_{12,R}(L) > \Phi_D + 0.025$$

An exact feasible flow proves that no radius choice can pass.

Refine genuine source labels at four regions

At $B = \{2,4,7,12\}$ retain RIGHT versus CROSS/LEFT.
15 nonempty RIGHT subsets $+$ 25 remaining anchors.

These forty branches cover every non-CROSS source string.

One shared rational radius vector per branch

$$\Phi_D > 19.90751095350, \quad \max_B G_B(L^B) < 19.85303956990$$

Certified gap > 0.04; exact data and explicit interval errors.
The general cover theorem gives the actual filled-volume limit.

General target: every eligible original plat

Prove a strict optimized bound for each genuine non-CROSS sector.
Fractional one-sided flows still need a global volume inequality.
